

## Oxides of Nitrogen

### ① Nitrous oxide, N<sub>2</sub>O

Preparation It may be prepared by reducing NO with moist iron filings or by heating NH<sub>4</sub>NO<sub>3</sub>.

It may also be prepared by heating a mixture of NaNO<sub>3</sub> and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> or NH<sub>4</sub>Cl

### Properties

- (i) Davy (1799) has called this gas laughing gas as it produces hysterical laughter on inhalation. Continuous inhalation causes insensibility to pain and finally death.
- (ii) It is colourless gas with a faint sweetish odour and taste. (m.p. = -90.8 °C, b.p. = 88.7 °C)
- (iii) It is appreciably soluble in water and more so in alcohol but is insoluble in hot water. The aqueous solution is neutral and does not behave as the anhydride of hyponitrous acid (H<sub>2</sub>N<sub>2</sub>O<sub>2</sub>), although it is formed by its decomposition.

N<sub>2</sub>O is a neutral oxide.

(iv) Decomposition When heated,  $N_2O$  gets decomposed into  $N_2$  and  $O_2$ .

The gas is also decomposed by electric sparks.

(v) Reduction Burnish pieces of P, C, S etc. burn brilliantly in  $N_2O$  gas and free  $N_2$  is evolved, i.e.  $N_2O$  is reduced to  $N_2$ .

When passed over hot Cu,  $N_2O$  is reduced to  $N_2$ .

## ② Nitric oxide (NO)

### Preparation

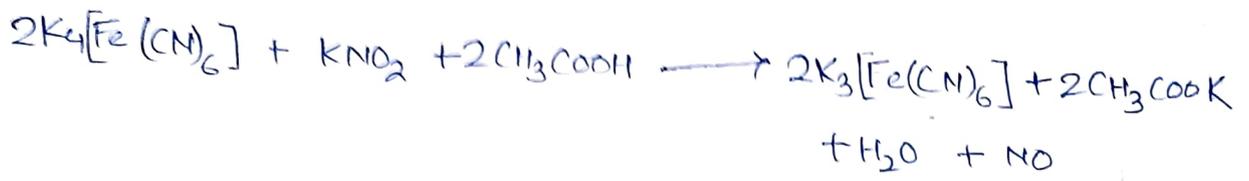

(i) In the laboratory, NO is obtained by the action of cold dil.  $HNO_3$  on Cu.

(ii) Pure NO is obtained by the action of  $NaNO_2$  solution on an acidified solution of KI

or by dropping a solution of  $K_4[Fe(CN)_6]$  and  $NaNO_2$  into dil.  $(CH_3COOH)$ .

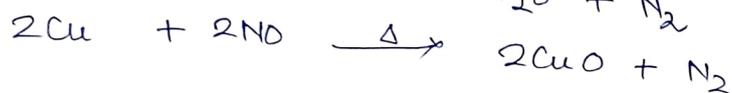

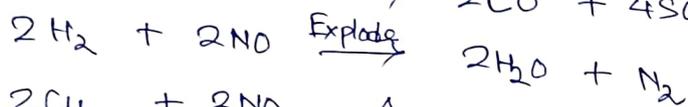

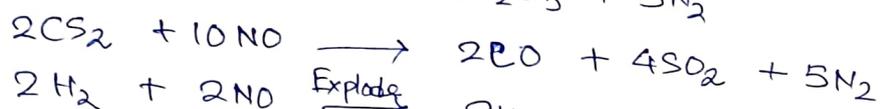

### Properties

- (i) NO is colourless gas which is slightly heavier than air.
- (ii) It is only sparingly soluble in water and is neutral oxide like  $N_2O$ .
- (iii) Liquid NO is blue in colour and boils at  $-151.7^\circ C$ . At  $-163.6^\circ C$  it freezes to blue solid.
- (iv) Action of solid  $NO_2$  The action of solid  $NO_2$  cooled in liquid air gives  $N_2O_3$ .

### (v) Reduction

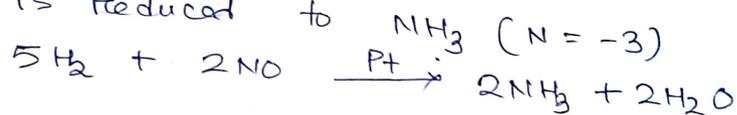

- (a) Burning phosphorus,  $CS_2$  vapour,  $H_2$  and heated metals (eg. Cu, Fe, Ni, Na etc.) reduce NO ( $N = +2$ ) and  $N_2$  ( $N = 0$ ).

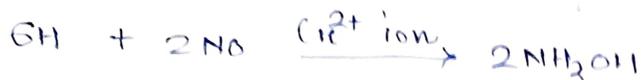

- (b)  $H_2SO_3$  and moist Fe filings reduce NO ( $N = +2$ ) to  $N_2O$  ( $N = +1$ ).

- (c) When heated with  $H_2$  in presence of Pt metal, NO ( $N = +2$ ) is reduced to  $NH_3$  ( $N = -3$ )

(d) Chromous ion ( $\text{Cr}^{2+}$ ) reduces  $\text{NO}$  ( $N = +2$ ) to  $\text{NH}_2\text{OH}$  ( $N = -1$ ).

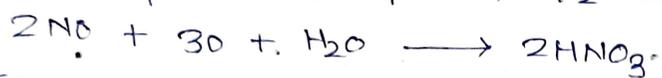

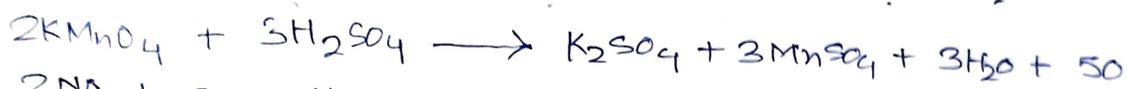

(e) Alkaline solution of  $\text{SnCl}_2$  reduces  $\text{NO}$  to potassium hyponitrite ( $\text{K}_2\text{N}_2\text{O}_2$ ).

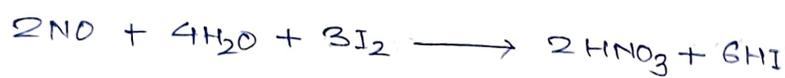

(vi) Oxidation

(a) Acidified solution of  $\text{KMnO}_4$  and dil. solution of  $\text{I}_2$  oxidise  $\text{NO}$  ( $N = +2$ ) to  $\text{HNO}_3$  ( $N = +5$ ).

This reaction is quantitative and is used for the estimation of  $\text{NO}$ .

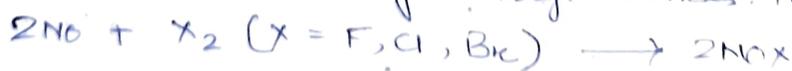

(b) Conc.  $\text{HNO}_3$  and  $\text{O}_2$  oxidise  $\text{NO}$  ( $N = +2$ ) to  $\text{NO}_2$  ( $N = +4$ )

(vii) Absorption by  $\text{FeSO}_4$ :  $\text{FeSO}_4$  solution absorbs  $\text{NO}$ , forming brown nitrosoferrous sulphate,  $(\text{NO})\text{FeSO}_4$

(viii) Action of halogens: Excepting  $\text{I}_2$ ,  $\text{F}_2$ ,  $\text{Cl}_2$  and  $\text{Br}_2$  react with  $\text{NO}$  and give corresponding nitrosyl halides,  $\text{NOX}$ .

## Nitrogen dioxide (NO<sub>2</sub>) and dinitrogen tetroxide (N<sub>2</sub>O<sub>4</sub>)

Preparation .1) NO<sub>2</sub> is prepared by mixing NO with O<sub>2</sub>.

2) By heating dry powdered Pb(NO<sub>3</sub>)<sub>2</sub> in hard glass tube.

3) By the action of conc. HNO<sub>3</sub> on Cu or Bi.

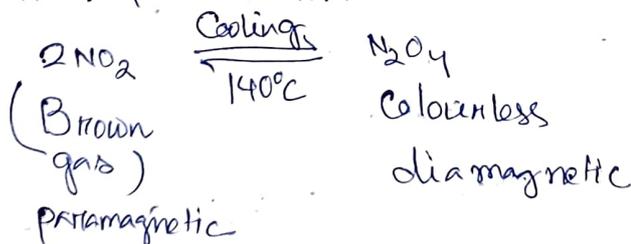

4) By heating nitroso sulphuric acid (NO)HSO<sub>4</sub> with dry KNO<sub>3</sub>.

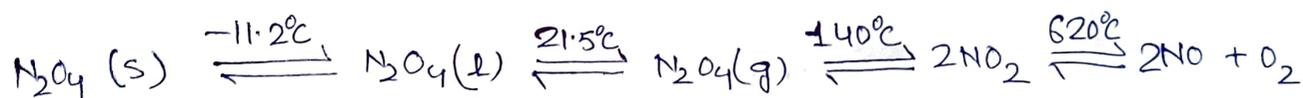

### Properties

(i) NO<sub>2</sub> is brown while N<sub>2</sub>O<sub>4</sub> is colourless.

(ii) Action of heat: NO<sub>2</sub> and N<sub>2</sub>O<sub>4</sub> exist in a temperature dependent equilibrium.

In the solid state, the oxide is entirely N<sub>2</sub>O<sub>4</sub> which appears to be colourless. At -11.2°C the solid N<sub>2</sub>O<sub>4</sub> melts and is converted into N<sub>2</sub>O<sub>4</sub> liquid. At 21.5°C N<sub>2</sub>O<sub>4</sub> is present as reddish brown vapour. At 140°C the oxide is present as NO<sub>2</sub>. At 620°C NO<sub>2</sub> dissociates into NO and O<sub>2</sub>. Reverse changes takes place on cooling.

Colourless

(iii) Action of metals and non-metals: Heated sodium burns in  $\text{NO}_2$  while potassium inflames spontaneously in the gas.

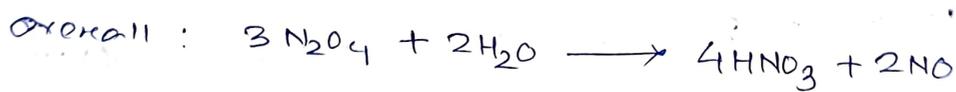

Strongly burning P and C burn in it because at high temperature,  $\text{NO}_2$  dissociates into  $\text{NO}$  and  $\text{O}_2$ .

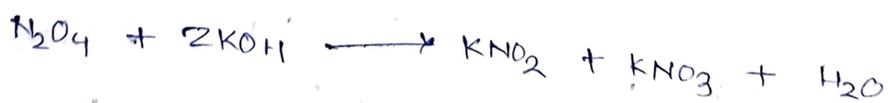

(iv) Acidic nature:  $\text{N}_2\text{O}_4$  is an acidic oxide, since it dissolves in  $\text{H}_2\text{O}$  and gives a mixture of  $\text{HNO}_2$  and  $\text{HNO}_3$ . Thus  $\text{N}_2\text{O}_4$  is called a mixed acid anhydride.

$\text{HNO}_2$  produced as above decomposes into  $\text{HNO}_3$  and  $\text{NO}$ .

$\text{N}_2\text{O}_4$  is absorbed by an alkali, forming a mixture of nitrite and nitrate.

(v) Action of conc.  $\text{H}_2\text{SO}_4$ : Conc.  $\text{H}_2\text{SO}_4$  absorbs  $\text{N}_2\text{O}_4$  and forms nitroso sulphuric acid,  $(\text{NO})\text{HSO}_4$  and  $\text{HNO}_3$

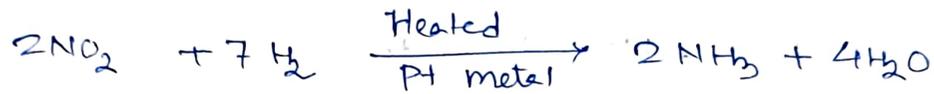

(vi) Oxidising Properties (Reduction).

(a)  $\text{NO}_2$  ( $\text{N} = +4$ ) oxidises  $\text{SO}_2$  to  $\text{H}_2\text{SO}_4$  in presence of  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{S}$  to  $\text{S}$ ,  $\text{CO}$  to  $\text{CO}_2$  and liberates  $\text{I}_2$  from  $\text{KI}$  solution and itself reduces to  $\text{NO}$  ( $\text{N} = +2$ )

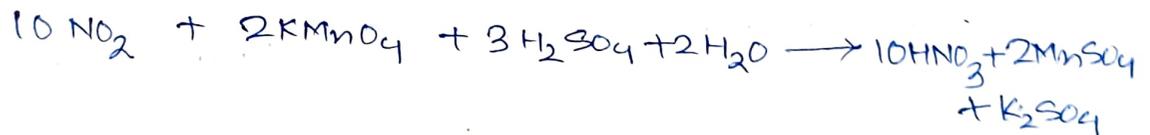

(b)  $\text{NO}_2$  (N = +4) oxidises  $\text{H}_2$  (H = 0) to  $\text{H}_2\text{O}$  (H = +1) and is reduced to  $\text{NH}_3$  (N = -3)

(c)  $\text{NO}_2$  (N = +4) oxidises Cu (Cu = 0) heated to bright redness to  $\text{CuO}$  (Cu = +2) and itself gets reduced to  $\text{N}_2$  (N = 0)

(vii) Oxidation:  $\text{NO}_2$  (N = +4) is oxidised to  $\text{HNO}_3$  (N = +5) by means of acidified  $\text{KMnO}_4$  solution.

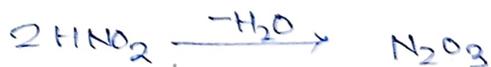

(viii) Action of ozonised  $\text{O}_2$ : When ozonised  $\text{O}_2$  (ie.  $\text{O}_3$ ) is passed into cooled liquid  $\text{N}_2\text{O}_4$ ,  $\text{N}_2\text{O}_5$  is obtained.

Dinitrogen trioxide or nitrogen sesquioxide,  $N_2O_3$

It is considered as anhydride of nitrous acid.

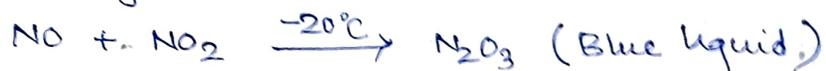

### Preparation

(i) By the action of copper on 5N nitric acid.

(ii) By cooling (below  $-20^\circ C$ ) a mixture (2:1) of nitric oxide and nitrogen dioxide in a tube.

(iii) By the distillation of a mixture of arsenous oxide ( $As_4O_6$ ) and 60%  $HNO_3$  by collecting the  $N_2O_3$  vapours in a U-tube, cooled in a freezing mixture.

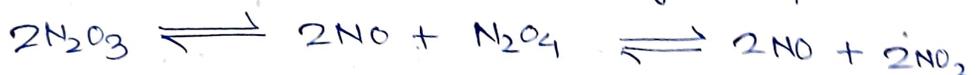

### Properties

(i) Solid  $N_2O_3$  forms blue crystals (m.p. =  $-120^\circ C$ )

(ii) It boils at  $3.5^\circ C$  with decomposition.

(iii) It decomposes on melting as follows—

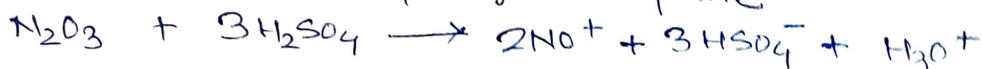

(iv) It dissolves in water to form nitrous acid,  $HNO_2$

(v) It reacts with bases to form nitrites.

(vi) When treated with concentrated sulphuric acid, blue colour of  $N_2O_3$  disappears due to the formation of fully ionised nitrosonium hydrogen sulphate

## Dinitrogen Pentoxide $N_2O_5$

### Preparation

(i) When conc.  $HNO_3$  is distilled with phosphorus pentoxide in a glass retort at  $70^\circ C$ , we get  $N_2O_5$

(ii) By passing ozone through liquid  $N_2O_4$

(iii) By the action of  $Cl_2$  on heated dry silver nitrate.

### Properties

(i) It is a white solid, mp. =  $30^\circ C$ , b.p. =  $47^\circ C$

(ii) It decomposes above  $30^\circ C$  and explodes when heated rapidly.

(iii) It is an anhydride of nitric acid because it dissolves in water to form this acid.

(iv) As an oxidant

(a) It oxidises iodine to iodine pentoxide.

(b) It oxidises all organic substances like cork, rubber etc. and destroys them.

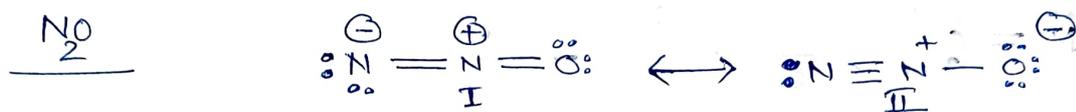

(v) It reacts with alkalis to form nitrates.

(vi) It ionises, in conc.  $\text{H}_2\text{SO}_4$  to form nitronium ion,  $\text{NO}_2^+$ .

## Structure

This molecule is linear and unsymmetrical having a small dipole moment. It is explained by considering it as a resonance hybrid of structure I and II. The bond lengths are

In  $\text{N}_2\text{O}$ , both nitrogen and oxygen atoms are considered to use  $sp$ -hybrid orbitals. The molecule is, thus, considered to have two sigma bonds. The two pairs of delocalised  $\pi$ -electrons extend over three atoms (N, N, and O)

NO

Valence bond theory

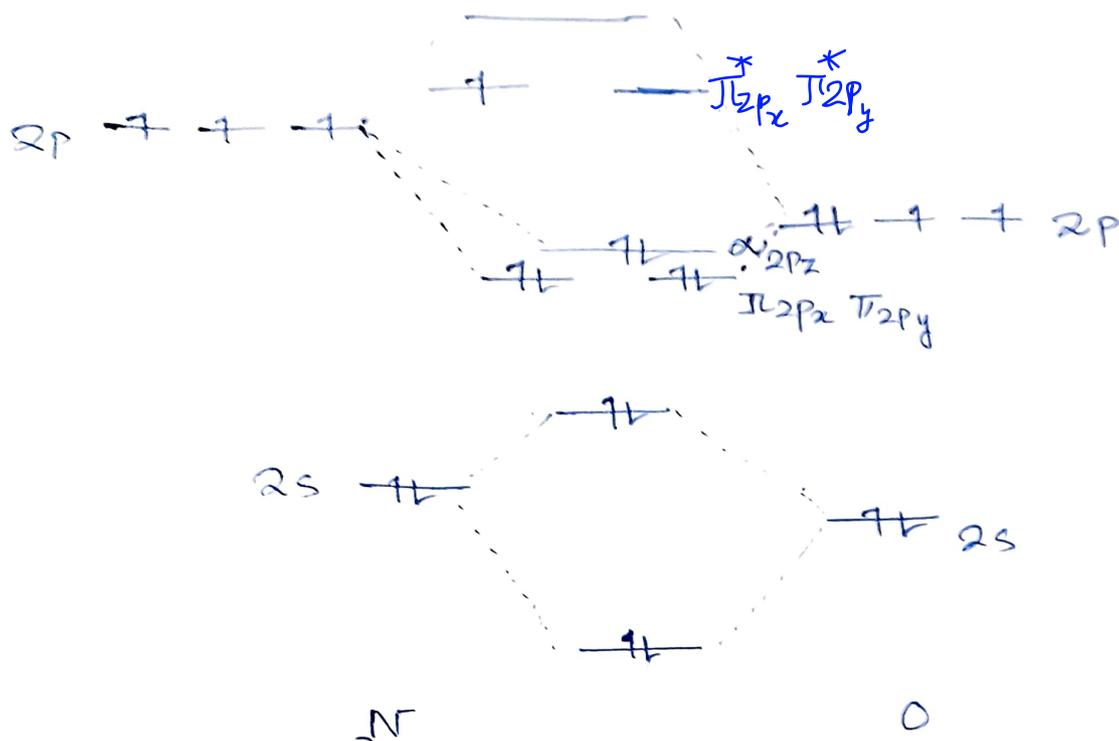

One N atom ( $1s^2 2s^2 2p^3$ ) and one O atom ( $1s^2, 2s^2, 2p^4$ ) have total 11 valence electrons.

The unpaired electrons of NO is spread over the whole molecule. It is represented as the average of the following structures.

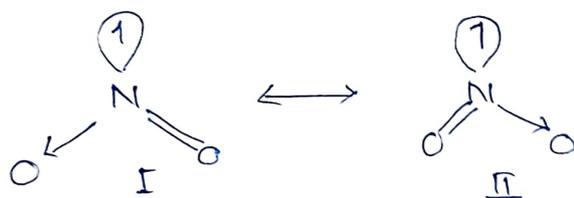

The N-O bond length is  $1.10 \text{ \AA}$ .

# Molecular Orbital theory

$$\text{Bond order} = \frac{8 - 3}{2} = 2.5$$

NO<sub>2</sub>

The electron diffraction studies have revealed that monomeric dioxide, NO<sub>2</sub> is angular with bond angle ONO equal to 134°. It is considered as a resonance hybrid of the structure I and II.
